NAVISIO.AI

"The complete suite for insurance intermediaries"

Team Leader

Simone Alberto

CTO & Co-Founder

Politecnico di Torino

Computer Engineer from Politecnico di Torino, with over 6 years of experience gained within brokerage firms.

Sisal Saluzzo Broker

Luca Alotto

CIO & COO

Università di Torino

Graduated in Economics from the University of Turin, with 11 years of experience in the ICT and IT consulting sector.

LEASYS FCA BANK enerbrain

The team is completed by 10 people across Product, IT and Sales

Problems that have persisted for 30 years

The sector is under pressure: margins are shrinking, costs are rising.

70%

of the time spent on activities not related to distribution, but to low added value tasks

80%

of intermediaries report a shortage of staff and difficulty finding qualified people

10.000 €

average annual cost per intermediary

There is no commercial standardisation

Distribution networks operate in isolation from the parent company's guidelines.

Source: Trend emergenti e competenze al centro della ricerca EY – IIA “Elementi trasformativi nel settore assicurativo”

Traditional insurance sales process

A manual, fragmented and expensive process that consumes valuable time every day.

Collection & Analysis 1

The client submits a request. The intermediary must manually gather all the required documents.

Time spent:
4/5 h

Comparison 2

The intermediary compares products manually and prepares quotes and proposals for the client.

Time spent:
3/4 h

Sale 3

The intermediary manually assembles the commercial proposal and presents it to the client.

Time spent:
1/2 h

Average total: 8/9 hours

Workflow with general-purpose AI

A process that appears faster but introduces risks and wasted time.

Il flusso di lavoro con AI Generaliste

Prompting 1

The intermediary must copy and paste documents into general-purpose LLMs, working from scratch every time.

Time spent:
5-10 min per document

Verification 2

Because general-purpose LLMs are not trained on the insurance domain, every output must be manually checked for errors and inconsistencies.

Time spent:
30-40 min per check

Adaptation 3

The output is generic and must be adapted to the specific requirements of each insurer.

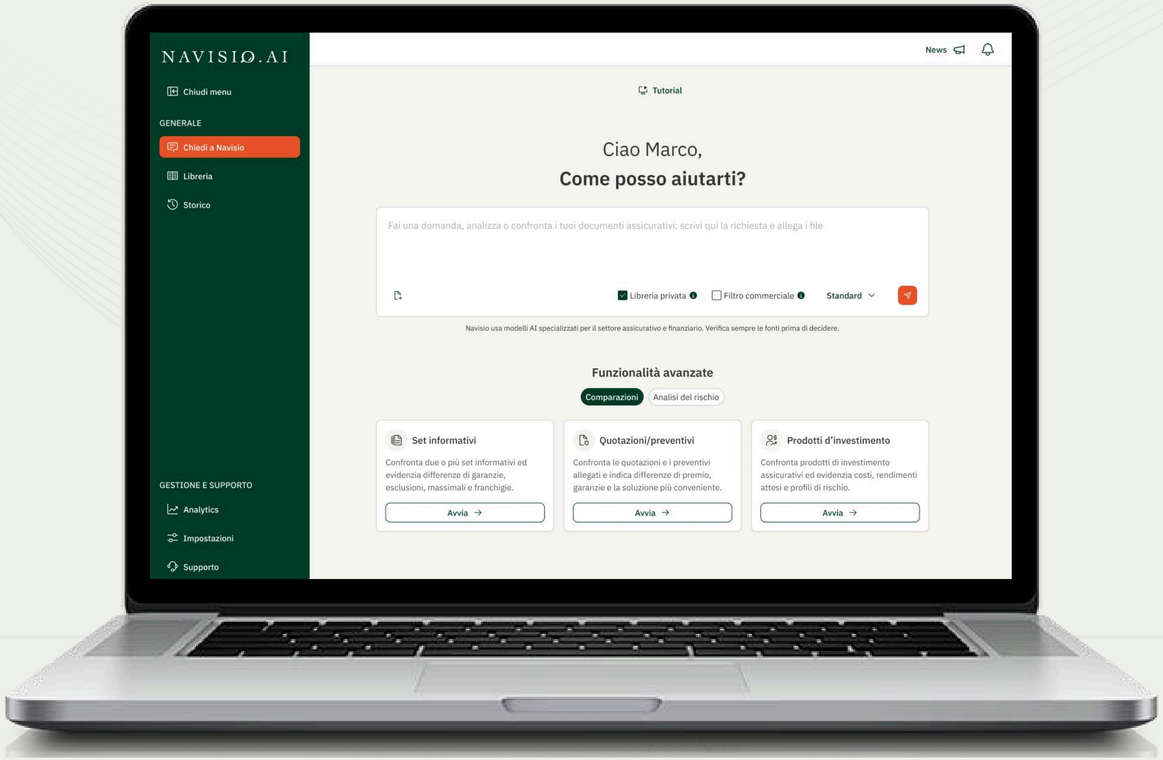

Time spent:
20-30 min per adaptation

Key Risks

- **General-purpose models process sensitive client data for training purposes.**
- **GDPR compliance is not guaranteed.**

Navisio is the agentic platform

Built specifically for the **insurance market.**
It **extends** the **managerial and operational capabilities** of intermediaries.

Workflow with Navisio

1. Delegate

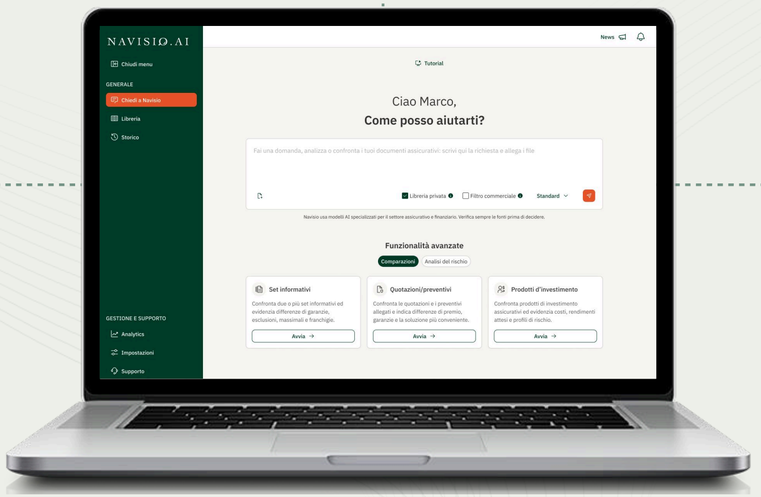

Agentic workflows handle every task delegated to them in your place

2. Analyse

Compare and assess policies with insurance-specific intelligence

3. Sell more

Higher quality advice for the client, greater trust and retention

From hours to minutes

In the largest market in the world, being present is no longer enough

Navisio will change the way people interact with the insurance market

NOW IT’S YOUR TURN

The Challenge

The challenge

Where we are today and what we are asking you to build

BACKGROUND

Navisio today runs on general-purpose LLMs accessed as an external service.

This limits control over data, reliability and regulatory compliance.

WHY IT MATTERS

In insurance, an unverifiable answer is not a bug: it is a liability.

YOUR MISSION

Design the transition to proprietary Small Language Models on a controlled cloud

Three pillars, one architecture

Not a prototype to ship an architecture to design

Technical and business trade-offs both count

Every choice must be justified with data

From general-purpose models to proprietary SLMs

	General-purpose LLMs	**Proprietary SLMs (Navisio)**
Number of parameters	Hundreds of billions	**Reduced, vertical domain**
Hosting and control	External, not controlled	**Private controlled cloud**
Domain performance	Generic	**Superior on the specific domain**

Fewer parameters, more control: specialisation beats brute force.

Three pillars of the challenge

Pillar 1

Data Extraction & Reliability

Objective · Method · Output

Pillar 2

Vertical Fine-Tuning

Objective · Method · Output

Pillar 3

Cloud Architecture & Control

Objective · Method · Output

Pillar 1: Data Extraction & Reliability

A manual, fragmented and inefficient process that consumes valuable hours every day

Unstructured documents

1

policies, PDFs, attachments

Extraction pipeline

2

deterministic, traceable

Verified knowledge base

3

every data point traceable to its source

OBJECTIVE	Eliminate model hallucinations
METHOD	Deterministic and verifiable extraction
EXPECTED OUTPUT	A solid, queryable knowledge base

Pillar 2: Vertical Fine-Tuning

Specialise the model on insurance language

Base model

conoscenza enciclopedica generica

1

Vertical training

ex. LoRA o QLoRA

2

Specialised model

insurance comparison

3

OBJECTIVE	Understand the language of technical and commercial comparison
METHOD	A training strategy, e.g. LoRA or QLoRA
CONSTRAINT	Shed the superfluous encyclopaedic knowledge of public models

Pillar 3: Cloud architecture & control

The model runs in a privately managed cloud

Data security

Reproducibility of results

Cost effective

Scalabile

vertically and horizontally

WHAT IT ENABLES → Managing the model lifecycle in-house

WHAT IT GUARANTEES → Compliance and consistent performance

Cross-cutting constraint: the architecture must scale according to cloud workloads without losing control or cost sustainability.

The expected result is not only improved performance.

From AI as an external service to AI as a core component of the software architecture

Data reliability approaching 100%

What you have to demonstrate

1. Model optimisation
2. Data engineering
3. Careful management of cloud resources

In order to

outperform the brute force of general-purpose models

Navisio Stack

Technologies you will be working with
